week-11-lesson-1

task-1
Type in the Program 9.2 Counting the Characters in a String from the book. Change it so instead of the preset string variables, users can enter two strings.

task-2
Type in the Program 9.3 Concatenating Character Arrays from the book. Change it so instead of the preset string variables, users can enter two strings.

task-3
4. Write a function called substring() to extract a portion of a character string. The function should be called as follows: `substring (source, start, count, result);`
where source is the character string from which you are extracting the substring, start is an index number into source indicating the first character of the substring, count is the number of characters to be extracted from the source string, and result is an array of characters that is to contain the extracted substring. For example, the call `substring ("character", 4, 3, result);`
extracts the substring "act" (three characters starting with character number 4) from the string "character" and places the result in result.
Be certain the function inserts a null character at the end of the substring in the result array. Also, have the function check that the requested number of characters does, in fact, exist in the string. If this is not the case, have the function end the substring when it reaches the end of the source string. So, for example, a call such as `substring ("two words", 4, 20, result);` should just place the string “words” inside the result array, even though 20 characters were requested by the call.

task-4
Write a function called uppercase() that converts all lowercase characters in a string into their uppercase equivalents.

task-5
Write a function called lowercase() that converts all uppercase characters in a string into their lowercase equivalents.

task-6
Write a program that inputs several lines of text and a search character and uses function strchr to determine the total occurrences of the character in the lines of text.

task-7
Write a program that inputs several lines of text and uses strtok to count the total number of words. Assume that the words are separated by either spaces or newline characters.

task-8
Write a program that reads a series of strings and prints only those strings beginning with the letter “b.”

task-9
Write a program that reads a series of strings and prints only those strings that end with the letters “ed.”

task-10
Type in the Program 9.8 Counting Words in a Piece of Text. Compile, run and understand.
