week-9-lesson-1

task-1

Declare a function that accepts a size and one dimensional int array and fills the accepted array. You can fill it with any rule like `a[i] = i+1`. Insert the function before the main function. Declare another function after the main function, which accepts a size of one-dimensional int array, the array and prints the values. Call these functions several times.

task-2

Declare a function that accepts a size and two dimensional int array and fills the accepted array. Insert the function before the main function. Declare another function after the main function, which accepts a size of two-dimensional int array, the array and prints the values.

Declare another function with the same implementation (printing array) by declaring only column size and keep the row size empty. Call these functions several times.

```
function_1(int rows, int columns, a[rows][columns])
function_2(int columns, a[][columns])
```

task-3

Declare a global variable and a new function function_1. Update the value from the main function and from the function_1 and from main again. Print the result after each update.

task-4

Declare a new function and two int variables. Make one of them static. Print the values and increment both variables inside the function. Call the function 3 times.

task-5

Write a function which accepts size and an array and generates an array values with that size and returns. Write another function that accepts an array and sorts it. Print out each step of the function during the sorting process. How is the array changing ?

task-6

Write functions which accept an array and return its minimum, maximum, average values and sum.
